Part I

introduction

Chapter 1

design constraints

xh is designed to be a powerful and ergonomic interface to multiple systems, many of which are remote. As such, it's subject to programming language, shell, and distributed-systems constraints:

1. xh will be used for real programming. (Initial assumption)
2. xh will be used as a shell. (Initial assumption)
3. xh will be used to manage any machine on which you have a login, which could be hundreds or thousands. (Initial assumption)
4. You will not always have root access to machines you want to use, and they may have different architectures. (Initial assumption)
5. xh should approach the limit of ergonomic efficiency as it learns more about you. (Initial assumption)
6. xh should never compromise your security, provided you understand what it's doing. (Initial assumption)
7. It should be possible to write a "hello world" HTTP server on one line. (Initial assumption, 1, 2)
8. It should be possible to preview the evaluation of any well-formed expression without causing side-effects. (Initial assumption, 2, 5, 11)
9. xh should never cause a dealbreaking performance problem. (Initial assumption, 1, 5)
10. Connections between machines may die at any time, and remain down for arbitrarily long. xh must never become unresponsive when this happens, and any data coming from those machines should block until it is available again (i.e. xh's behavior should be invariant with connection failures). (Initial assumption, 1, 2, 3)

11. Debugging should require little or no effort; all error cases should be trivially obvious. (Initial assumption, 1, 3, 5)
12. An xh instance should trivially function as a database; there should be no distinction between data in memory and data on disk. (Initial assumption, 1, 5, 11, 19, 9)
13. xh should use every keystroke to build/refine a model it uses to predict future keystrokes and commands. (5)
14. The likelihood that xh forgets anything from your command history should be inversely proportional to the amount of effort required to re-type/recreate it. (5, 13)
15. xh must provide a way to accept input and execute commands without updating its prediction model. (6)
16. xh should be able to submit an encrypted version of its current state to HTTP services like Github gists or pastebin. (5, 6, 10, 52, 53)
17. xh-script needs to feel like a regular shell for most purposes. (2)
18. xh-script should be fundamentally imperative. (1, 2, 17)
19. xh must never run out of memory or swap pages to disk, regardless of what you tell it to do. (1, 2, 9, 5)
20. xh must respond to every keystroke within 20ms; therefore, SSH must be used only for nonblocking RPC requests (i.e. the shell always runs locally). (2, 9, 5)
21. All resources, local and remote, must be uniformly accessible; i.e. auto-complete, filename substitution, etc, must all just work (up to random access, which is impossible without FUSE or similar). (2, 3, 5)
22. xh-script uses prefix notation. (2)
23. xh-script quasiquotes values by default. (2)
24. xh-script defines an unquote operator. (2, 23)
25. The xh runtime provides real, garbage-collected data structures. (1)
26. Every xh data structure has a quoted form. (25, 2, 11, 8)
27. Every xh data structure can be losslessly serialized. (2, 3, 12, 26, 55, 58)
28. Data structures have no identity and therefore are immutable. (3, 27)
29. xh-script must have access to machine-specific opaque resources like PIDs and file handles. (1, 2)

30. Each xh instance should implement a mutable symbol table with weak reference support, subject to semi-conservative distributed garbage collection. (28, 29, 19, 46)
31. Every piece of mutable state, including symbol tables, must have at most one authoritative copy (mutable state within xh is managed by a CP system). (10, 29, 30, 49)
32. An xh instance should be able to save checkpoints of itself in case of failure. If you do this, xh becomes an AP system. (10, 31)
33. xh's evaluator must support some kind of laziness. (1, 19, 21, 9)
34. Lazy values must have well-defined quoted forms and be losslessly serializable. (26, 27, 33, 49, 46)
35. All lazy values must be subject to introspection to identify why they haven't been realized. (11, 9, 10, 20, 33, 48)
36. xh must be able to partially evaluate expressions that contain unknown quantities. (8, 33, 35, 34)
37. xh-script code should be a reasonable data storage format. (2, 36)
38. xh-script must contain a library to parse itself. (37)
39. xh-script must be homoiconic. (37, 38, 43, 45)
40. xh should be able to compile any function to C, compile it if the host has a C compiler, and transparently migrate execution into this process. (1, 49, 9)
41. xh should be able to compile any function to Perl rather than interpreting its execution. (1, 4, 9)
42. xh should be able to compile any function to Javascript so that browser sessions can transparently become computing nodes. (1, 3, 9)
43. xh should follow a bootstrapped self-hosting runtime model. (40, 41, 42, 45)
44. xh-script should be executed by a profiling/tracing dynamic compiler that automatically compiles certain pieces of code to alternative forms like Perl or C. (9)
45. The xh compiler should optimize data structure representations for the backend being targeted. (9, 49, 44)
46. xh needs to implement its own heap and memory manager, and swap values to disk without blocking. (1, 19, 12, 56)

47. xh should implement its own threading model to accommodate blocked IO requests. (2, 3, 7, 33, 46)
48. xh threads should be subject to scheduling that reflects the user's priorities. (2, 3, 33, 47)
49. Running threads must be transparently portable between machines and compiled backends. (3, 47, 44, 45, 48)
50. All machine-specific references must encode the machine for which they are defined. (29, 49)
51. Every xh instance must have a unique ID, ideally one that can be typed easily. (5, 50)
52. xh needs to be able to self-install on remote machines with no intervention (assuming you have a passwordless SSH connection). (3, 4)
53. You should be able to upload your xh image to a website and then install it with a command like this: `curl me.com/xh | perl`. (3, 4)
54. Your settings should be present as soon as you download your image, so the image must be self-modifying and contain your settings. (3, 5, 13, 52, 53)
55. Your settings should be able to contain any value you can create from the REPL (with the caveat that some are defined only with respect to a specific machine). (1, 2, 5, 25, 53)
56. xh should probably be written in Perl 5. (3, 4, 52, 53, 54)
57. xh can't have any dependencies on CPAN modules, or anything else that isn't in the core library. (3, 4, 52)
58. It should be possible to address variables defined within xh images (as files or network locations). (54, 55)
59. xh's RPC protocol must work via stdin/out communication over an SSH channel to a remote instance of itself. (3, 6, 52, 20, 21)
60. xh's RPC protocol must support request multiplexing. (3, 9, 20, 21, 33, 59)
61. Two xh servers on the same host should automatically connect to each other. This allows a server-only machine to act as a VPN. (3, 4, 59, 63)
62. xh should create a UNIX domain socket to listen for other same-machine instances. (6, 61)
63. xh's network topology should forward requests transitively. (3, 4, 59)
64. xh should implement a network optimizer that responds to observations it makes about latency and throughput. (9, 59, 63)

Chapter 2

self-replication

Listing 2.1 boot/xh-header

```
1  #!/usr/bin/env perl
2  BEGIN {eval(our $xh_bootstrap = q{
3  # xh | https://github.com/spencertipping/xh
4  # Copyright (C) 2014, Spencer Tipping
5  # Licensed under the terms of the MIT source code license
6
7  # For the benefit of HTML viewers (long story):
8  # <body style='display:none'>
9  # <script src='http://spencertipping.com/xh/page.js'></script>
10 use 5.014;
11 package xh;
12 our %modules;
13 our @module_ordering;
14 our %eval_numbers = (1 => '$xh_bootstrap');
15
16 sub with_eval_rewriting(&) {
17     my @result = eval {$_[0]->(@_[1..$#])};
18     $@ =~ s/\(eval (\d+)\)/$eval_numbers{$1}/eg if $@;
19     die $@ if $@;
20     @result;
21 }
22
23 sub named_eval {
24     my ($name, $code) = @_;
25     $eval_numbers{$1 + 1} = $name if eval('__FILE__') =~ /\(eval (\d+)\)/;
26     with_eval_rewriting {eval $code};
27 }
28
29 our %compilers = (pl => sub {
```

```

30  my $package = $_[0] =~ s/\./::/gr;
31  named_eval $_[0], "{package ::$package;\n$_[1]\n}";
32  die "error compiling module $_[0]: $@" if $@;
33  });
34
35  sub defmodule {
36      my ($name, $code, @args) = @_;
37      chomp($modules{$name} = $code);
38      push @module_ordering, $name;
39      my ($base, $extension) = split /\.(?w+)$/, $name;
40      die "undefined module extension '$extension' for $name"
41          unless exists $compilers{$extension};
42      $compilers{$extension}->($base, $code, @args);
43  }
44
45  chomp($modules{bootstrap} = $::xh_bootstrap);
46  undef $::xh_bootstrap;

```

At this point we need a way to reproduce the image. Since the bootstrap code is already stored, we can just wrap it and each defined module into an appropriate BEGIN block.

Listing 2.2 boot/xh-header (continued)

```

1  sub image {
2      my @pieces = "#!/usr/bin/env perl";
3      push @pieces, "BEGIN {eval(our \${xh_bootstrap} = <<'_')}",
4                      $modules{bootstrap},
5                      '_';
6      push @pieces, "BEGIN {xh::defmodule('$_', <<'_')}",
7                      $modules{$_},
8                      '_ ' for @module_ordering;
9      push @pieces, "xh::main::main;\n__DATA__";
10     join "\n", @pieces;
11 }
12 }}

```

Chapter 3

reader

xh-script has a reader just like Lisp does. This makes it easier to factor the runtime: the reader is invariant with the semantics of the language under any given interpreter/compiler. For simplicity, this reader does not stream its output. Instead, it emits a full quoted data structure hierarchy in OO format.

Listing 3.1 src/v.pl

```
1 BEGIN {xh::defmodule('xh::v.pl', <<'_'')}
2 use parent qw/Exporter/;
3 our @EXPORT = qw/read/;
4
5 sub new {
6     my ($class, $type, $tag, @values) = @_ ;
7     bless [$type, $tag, @values], $class;
8 }
9 sub parse {
10     my @return_values;
11     my @context = (\@return_values);
12
13     while ($_[0] =~ /\G (? \s* | #.* )*
14             (? ( ?<tag> [^\s()\[\]\{\}"]+ )?
15                 (? ( ?<listopen> \[
16                     | ( ?<vectoropen> \[
17                     | ( ?<mapopen> \{
18                     | "( ?<dstring> (? [^"]* | \\ [ \s \S ] ) )"
19                     | ' ( ?<sstring> (? [^']* | \\ [ \s \S ] ) ) '
20                     | ( ?<word> (? [^\s()\[\]\{\}"]+ | \\. )+ )
21                     | ( ?<listclose> \] )
22                     | ( ?<vectorclose> \] )
23                     | ( ?<mapclose> \} ) ) ) /xmg) {
24         my $opener = ${listopen} // ${vectoropen} // ${mapopen};
25         if (defined ${word}) {
```

```

26     push @{$context[-1]}, ${word};
27 } elsif (defined ${dstring}) {
28     push @{$context[-1]}, xh::v->new('"'', ${tag}, ${dstring});
29 } elsif (defined ${sstring}) {
30     push @{$context[-1]}, xh::v->new('"'', ${tag}, ${sstring});
31 } elsif (defined $opener) {
32     my $new_container = xh::v->new($opener, ${tag});
33     push @{$context[-1]}, $new_container;
34     push @context, $new_container;
35 } elsif (defined(${listclose} // ${vectorclose} // ${mapclose})) {
36     my $popped = pop @context;
37     push @{$context[-1]}, $popped;
38 }
39 }
40 @return_values;
41 }
42 -

```

Listing 3.2 src/v/type-definition.pl

```

1 use parent qw/Exporter/;
2 our @EXPORT = qw/read/;
3
4 sub new {
5     my ($class, $type, $tag, @values) = @_;
6     bless [$type, $tag, @values], $class;
7 }

```

Listing 3.3 src/v/reader.pl

```

1 sub parse {
2     my @return_values;
3     my @context = (\@return_values);
4
5     while ($_[0] =~ /\G (? \s* | #.* )*
6           (? ( ?<tag> [^\s()\[\]\{\}\"]+ )?
7             (? ( ?<listopen> \[
8                 | ( ?<vectoropen> \[
9                     | ( ?<mapopen> \{
10                        | "( ?<dstring> (? [^"]* | \\ [ \s \S ] ) )"
11                        | '( ?<sstring> (? [^']* | \\ [ \s \S ] ) )'
12                        | ( ?<word> (? [^\s()\[\]\{\}\"] | \\. )+ )
13                        | ( ?<listclose> \] )
14                        | ( ?<vectorclose> \] )
15                        | ( ?<mapclose> \} ) ) ) /xmg) {
16     my $opener = ${listopen} // ${vectoropen} // ${mapopen};
17     if (defined ${word}) {

```

```

18     push @{$context[-1]}, ${word};
19 } elsif (defined ${dstring}) {
20     push @{$context[-1]}, xh::v->new('"'', ${tag}, ${dstring});
21 } elsif (defined ${sstring}) {
22     push @{$context[-1]}, xh::v->new('"'', ${tag}, ${sstring});
23 } elsif (defined $opener) {
24     my $new_container = xh::v->new($opener, ${tag});
25     push @{$context[-1]}, $new_container;
26     push @context, $new_container;
27 } elsif (defined(${listclose} // ${vectorclose} // ${mapclose})) {
28     my $popped = pop @context;
29     push @{$context[-1]}, $popped;
30 }
31 }
32 @return_values;
33 }

```
