                            7 # For the benefit of HTML viewers (long story):
                            8 # <body style='display:none'>
                            9 # <script src='http://spencertipping.com/xh/page.js'></script>
                           10 use 5.014;
                          11 package xh;
                          12 our %modules;
                          our @module_ordering;
                          our %eval_numbers = (1 => '$xh_bootstrap');
                          sub with_eval_rewriting(&) {
                                       my @result = eval {$_[0]->(@_[1..$#_])};
                                            0 = s/(eval (d+))/seval_numbers{1}/eg if 0;
                                            die $@ if $@;
                          19
                                            @result;
                          20
                          21 }
                          23 sub named_eval {
                                            my ($name, $code) = @_;
                                            \ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensuremath{\mbox{$}}\ensure
                                            with_eval_rewriting {eval $code};
                          26
                          27 }
                          28
                                     our %compilers = (pl => sub {
```

```
my package = [0] = s/\./::/gr;
30
     named_eval $[0], "{package :: package; \n\[1]\n}";
     die "error compiling module $_[0]: $@" if $@;
   });
33
34
   sub defmodule {
35
     my ($name, $code, @args) = @_;
36
     chomp($modules{$name} = $code);
     push @module_ordering, $name;
38
     my (\$base, \$extension) = split / \. (\w+\$)/, \$name;
     die "undefined module extension '$extension' for $name"
40
       unless exists $compilers{$extension};
     $compilers{$extension}->($base, $code, @args);
42
43
44
   chomp($modules{bootstrap} = $::xh_bootstrap);
   undef $::xh_bootstrap;
```

At this point we need a way to reproduce the image. Since the bootstrap code is already stored, we can just wrap it and each defined module into an appropriate BEGIN block.

```
Listing 1.2 boot/xh-header (continued)
```

Chapter 2

SSH routing fabric

xh does all of its distributed communication over SSH stdin/stdout tunnels (since remote hosts may have port forwarding disabled), which means that we need to implement a datagram format, routing logic, and a priority-aware traffic scheduler.

For simplicity, the only session type that's supported is RPC. The request and response each must fit into a single packet, which is size-limited to 64 kilobytes excluding the packet header. The fabric client will deal with larger requests and responses, but it will cause additional round-trips.

```
Listing 2.1 src/fabric.pl
        BEGIN {xh::defmodule('xh::fabric.pl', <<'_')}</pre>
        2 -- include src/fabric/dependencies.pl
        3 -- include src/fabric/state.pl
        4 -- include src/fabric/packet-format.pl
        5 -- include src/fabric/message-types.pl
        6 -- include src/fabric/standard-priorities.pl
          -- include src/fabric/routing-rpcs.pl
Listing 2.2 src/fabric/dependencies.pl
        use Sys::Hostname;
        use Time::HiRes qw/time/;
        3 use Digest::SHA qw/sha256/;
Listing 2.3 src/fabric/state.pl
           # Mutable state space definition for the routing fabric. You should create
        2 # one of these for every separate xh network you plan to interface with.
        4 sub fabric_client {
           my ($name, $bindings) = @_;
```

```
$name //= $ENV{USER} . '@' . hostname . '.local';
     return {rpc_bindings
                                => $bindings // {},
             instance_name
                                \Rightarrow $name.
8
              instance_id
                                => 0.
              edge_pipes
                                => {},
              network_topology => {},
              send_queue
                                => [],
12
                                => {},
              blocked_rpcs
              routing_cache
14
                                => {},
              packet_timings
                                => {}};
16
   }
   sub fabric_rpc_bind {
18
     my ($state, %bindings) = @_;
     my $bindings = $state->{rpc_bindings};
20
     $bindings->{$_} = $bindings{$_} for keys %bindings;
21
     $state;
22
23 }
```

2.1 Packet format

Packets and headers are written in binary, and all multibyte numbers are bigendian. The structure of a packet is:

```
data+header SHA-256:
                            32 bytes
packet identity nonce:
                            32 bytes
source xh instance ID:
                            4 bytes
destination xh instance ID: 4 bytes
packet creation time:
                            8 bytes (double) |
                                              | SHA applies to these bytes
data length:
                            2 bytes
message type:
                            1 byte
priority:
                            1 byte
deadline:
                            2 bytes
data:
                            <= 65535 bytes
```

The only reason we represent packet creation time as a double rather than as a 64-bit integer is that 64-bit integer support is not guaranteed within Perl. As a result, we have a somewhat awkward situation where all absolute times are encoded as doubles and all deltas as integers.

```
Listing 2.4 src/fabric/packet-format.pl

1 use constant header_pack_format => 'C32 N N d n C C n';
2 use constant signed_header_pack_format => 'C32 ' . header_pack_format;

3 use constant signed_header_length => 32 + 32+4+4+8+2+1+1+2;
```

```
use constant header_signature_length => 32;
   our $nonce_state = sha256(time . hostname);
   sub packet_nonce {$nonce_state = sha256(time . $nonce_state)}
   sub encode_packet {
10
     my ($state, $destination_name, $message_type, $priority, $deadline)
       = @_;
     die "data is too long: " . length($_[5]) . " (max is 65535 bytes)"
       if length $_[5] >= 65536;
14
     my $destination_id = $state->{routing_cache}{$destination_name};
     return undef unless defined $destination_id;
18
     my $header = pack header_pack_format, packet_nonce,
20
                                             $state->{instance_id},
                                             $destination_id->{endpoint_id},
                                             time,
22
                                             length $_[5],
24
                                             $message_type,
                                             $priority,
                                             $deadline;
26
     my $packet = $header . $_[5];
27
     sha256($packet) . $packet;
28
29
   }
30
   sub decode_packet_header {
     unpack signed_header_pack_format, $_[0];
32
33
   }
34
   sub signature_is_valid {
     my $sha = substr $_[0], 0, header_signature_length;
36
     $sha eq sha256(substr $_[0], header_signature_length);
37
38 }
```

message type is one of the following values:

- **0** Forgetful RPC request. The receiver should execute the code, but the sender will not await a reply. This is used internally by xh to maintain routing graph information and clock offsets.
- 1 Functional RPC request. This indicates that the receiver should execute the given code, encoded as text, and send a reply. The code may contain references that require further RPCs to be issued.
- 2 RPC reply after a successful invocation. The return value of the function is encoded in quoted form, and may require further dereferencing via RPC.

- 3 Callee-side RPC error; the reply is a partially-evaluated quoted value, where any unevaluated pieces represent errors.
- 4 Routing error or timeout; the routing fabric generates this to indicate that it has given up on getting a successful reply. If this happens, the sender will automatically re-send the RPC unless the deadline has expired.

priority and deadline are used for scheduling purposes. Zero is the highest priority, 65535 is the lowest. The deadline is used to indicate how timesensitive the packet is; the queueing order function used by the scheduler is $\frac{2^c}{s}$, where:

```
c = \frac{\Delta t - d}{16 + p}
\Delta t = \text{ms since packet was originally sent}
d = \text{the deadline}
p = \text{the priority}
s = \text{header} + \text{data size in bytes}
```

 Δt is an estimated quantity, since hosts will not, in general, have synchronized clocks. However, xh uses a protocol similar to NTP to estimate clock offsets for each instance. These clock offsets are used to coordinate instances on different hosts. (See 2.3.)

```
Listing 2.6 src/fabric/standard-priorities.pl
           use constant {realtime_priority => 0,
                         high_priority => 16,
                         normal_priority => 256,
                         low_priority
                                           => 32768};
           use constant {realtime_deadline
        6
                         imperceptible_deadline
                                                    => 20,
                         short_interactive_deadline => 50,
        8
                         long_interactive_deadline => 100,
        9
                         process_blocking_deadline => 250,
                         background_deadline
                                                    => 2000
                         far_deadline
                                                    => 32768};
        12
```

2.2 Routing logic

I assume the topology of xh instances will fit into memory. This won't be a problem for most installations; in practice, xh should be able to easily manage (and transfer data between) many hundreds of machines without slowing down. Each xh instance maintains a copy of the full routing graph, which includes information about edge timings.

The routing logic's job is to decide how to most effectively get packets from point A to point B, which, more formally, means minimizing the expected sum of delay costs. Doing this well involves a few factors:

- 1. An edge's average latency and throughput.
- 2. The variance in an edge's latency and throughput, absent xh traffic.
- 3. The impact of traffic on an edge's latency and throughput.

All of these are continuously measured and periodically propagated as network topology metadata. When this propagation happens, each instance recomputes its routing cache to pick up on any changes in optimal routes.

```
Listing 2.7 src/fabric/routing-rpcs.pl
    sub recompute_routing_cache {
        my ($state) = @_;
        }
}
```

2.3 Clock offset estimation
